OUR STAFF

We are scientists, engineers, data analysts, field technicians and educators with a shared passion for working in the evolving geology of Alaska. We are motivated by the reality that some of the great tragedies of our time are caused by earthquakes, as well as the knowledge that earthquakes are a powerful tool for understanding our landscape and the resources it contains.

National Tsunami Warning Center

November 30, 2018 · 🌐

As the shaking continues in southcentral Alaska, please take a minute to learn about aftershocks from the attached information sheet.

Understanding Aftershocks

The vigorous aftershock sequence following the **magnitude 7.0** earthquake that struck north of Anchorage this morning (November 30, 08:29 local) has southcentral Alaska residents understandably concerned as shaking rumbles on into evening.

Here are some key facts about aftershocks:

1. The rate of aftershocks decreases with time
2. The largest aftershock is **usually** around 1 magnitude smaller than the main shock (we may see around a magnitude 6 aftershock)
3. There are many more small aftershocks than large aftershocks

The USGS have released an aftershock forecast for the next week:

- Chance of a magnitude 7 or higher aftershock is 4%
- Chance of a magnitude 6 or higher aftershock is 27%. There may be up to 3 of these
- Chance of a magnitude 5 or greater aftershock is 78%. Possibly up to 23 of these
- There could be as many as 2,200 magnitude 3 or higher aftershocks!

Many people felt the M4.1 aftershock that occurred just after 11PM this evening. Here is the reviewed magnitude and location:

- Event situational awareness
- M_w is more reliable than m_l for large events
- concise summary of an event that can be pushed to the public

Method

- Regional moment tensor
- $\Delta \leq 500\text{km}$
- Antelope port of TDMT (Dreger, 2003)
- Uses Antelope Python libraries (Lindquist, 2008)
- Bandpass between 0.02 and 0.04 Hz
- $4.0 \leq M_w \leq 7.5$

“In the view of monitoring the long-period SWF [seismic wave field] presented above, a seismometer (or seismic station) can be considered as a machinery to correlate the long-period vibration with the vibration predicted by virtual sources.”

(Kawakatsu, 1998)

Python tool for preparing monitoring grids

- grid coordinates
- Finds unique source-receiver-offsets and azimuths
- Loads and filters required Green's functions
- Computes the gli for each grid point
- Easy to read and maintain

```

1  def gli(G):
3      # Use numpy to compute the generalised
      linear inverse
      G = G.transpose() # G is transposed by the
      Aurelie equations, so we flip it!
5      GTG = np.dot(G.transpose(), G)
      GTGI = np.linalg.inv(GTG)
7      GLI = np.dot(GTGI, G.transpose())

9      return GLI
# End the gli function

```

- **dbgridmt** is a skin for the gridmt dbwfproc task. Written in C.
 - Reads pre-recorded waveforms from an Antelope db
 - Is useful for testing gridmt or for quickly populating moment tensor catalogs from long time series
 - Easily configurable via standard Antelope parameter files,
- **orbgridmt** is a skin for the gridmt orbwfproc task.
 - Reads real-time data from an Antelope orb
 - This is the operational skin

gridmt skins

Easily configurable with standard Antelope parameter files

```

1 gridmt_params &Arr{
3 # Fundamental 'gridmt' parameters:
4     num_sta      3
5     num_pts     380
6     num_lat     23
7     num_lon     15
8     num_dep     16
9     num_iso     5
10    verbose      1
11
12 # Variance reduction threshold (%)
13 det_tol        55
  
```

dbgridmt.pf

gridmt is the computational heart of the scanner.

- Compares predicted and observed waveforms
- Announces detections
- Outputs hypocenter, M_w , and mechanism to a db, an orb, and as text
